BI 1	query	BI / read / 19			
BI 2	title	Interaction path between cities			
BI 3	pattern				
BI 4	desc.	<p>Given two Cities <i>city1</i>, <i>city2</i>, find Persons <i>person1</i>, <i>person2</i> living in these Cities (respectively) with the shortest <i>interaction path</i> between them. If there are multiple pairs of people with shortest paths having the same total weight, return all of them.</p> <p>The shortest path is computed using a weight between two Persons defined as the reciprocal of the number of interactions (direct reply Comments to a Message by the other Person). Therefore, more interactions imply a smaller weight.</p> <p><i>Note:</i> Interactions are counted both ways, i.e. if Alice writes 2 reply Comments to Bob's Messages and Bob writes 3 reply Comments to Alice's Messages, their total number of interactions is 5.</p>			
BI 5	params	1	city1Id	ID	(A) Small Cities within the same Country with many direct relationships between their inhabitants
BI 6		2	city2Id	ID	(B) Small Cities from different Countries with only a few direct relationships between their inhabitants
BI 7	result	1	person1.id	ID	R
BI 8		2	person2.id	ID	R
BI 9		3	totalWeight	32-bit Float	C
BI 10	sort	1	totalWeight	↑	
BI 11		2	person1.id	↑	
BI 12		3	person2.id	↑	
BI 13	limit	20			
BI 14	CPs	3.3, 7.6, 7.7, 8.4, 8.6			
BI 15	relevance	<p>Finding shortest paths between pairs of Persons in Cities can be implemented in theory with an <i>all-pairs shortest paths</i> algorithm. However, this needs to be executed on the whole Person-knows-Person graph (with edge weights derived from the number of interactions) so it is expected to be prohibitively expensive. A better approach is using multiple <i>single-source shortest path algorithms</i> (e.g. from the City with fewer inhabitants). Implementations can either pre-compute edge weights or compute them on-the-fly.</p>
